Supplementing Programmed Assisted Patient Narratives (PANs) with Graphs Using SAS

Faye Yeh, MS and Melvin Munsaka, PhD

Takeda Global Research and Development, Inc, Deerfield, IL

ABSTRACT

When addressing safety issues of concern, it is often necessary to provide narratives on specific patients. Indeed, the ICH-E3 guideline calls for provision of narratives of deaths, other serious adverse events, and certain other significant adverse events judged to be of special interest. To facilitate for this, it is useful to provide programmed assisted narratives (PANs) in the form of targeted patient profiles. PANs are also useful for internal safety review, safety monitoring, and data integrity checks. They are basically by-patient numeric and text listings organized by domain and include targeted data needed for narratives. They allow for consolidation of information about the important domains in one place without having to look at multiple listings for the subject's data. This may include patient identifier, demographic information, and other relevant information pertaining to the events of special interest, such as, concomitant and previous illnesses, details of timing and duration and relevant concomitant and previous medication. In order to get maximum benefit in writing the narratives and to quickly identify key characteristics of importance, it is useful to integrate numeric and text output in the PANs with graphs. The use of graphs allows for multidimensional data visualization and quick assessment of the relationship between data which may not be easy to pick out from text and listing format only. This paper will discuss the integration of numeric and text PANs with graphs using SAS. SAS code for integrating text and numeric output with graphs in the PANs will be illustrated.

INTRODUCTION

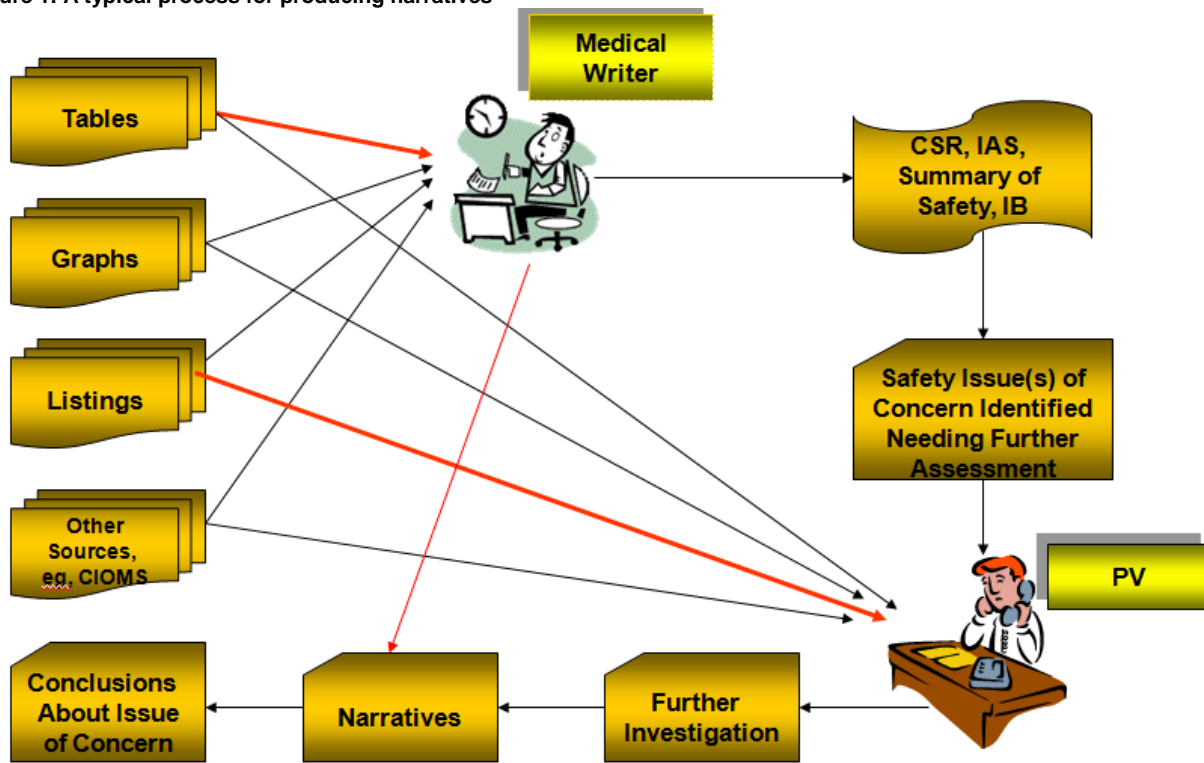

Establishing the safety profile of a drug is a key consideration and an important part of the drug development process. Typically, the primary sources of data for establishing the safety profile include safety tables, listings and graphs on AEs, laboratory data, vital signs, ECG, and other safety data sources. The ICH-E3 guideline calls for narratives of deaths, other serious adverse events, and certain other significant adverse events judged to be of special interest. To facilitate this, it is useful to provide programmed assisted narratives (PANs) in the form of targeted patient profiles. PANs are also useful for internal safety review, safety monitoring, and data integrity checks. Traditionally, PANs have been displayed in multiple tables and graphs separately and often in a disconnected fashion. The proposal been put forward here allows for the integration of text and graphical output allowing for multidimensional data visualization of a patient data and data values from multiple data domains which can aid in the assessment of patient safety. This paper will discuss the integration of alphanumeric PANs with graphs using SAS ODS and SAS GTL. SAS code for integrating text and numeric output with graphs in the PANs will be illustrated. Further, these outputs are easily customizable for specific study needs and hence can be used across different compounds or studies.

PATIENT NARRATIVES

Patient narratives are useful for conveying safety information in a concise and summary fashion. Narratives are a requirement for addressing safety concern of interest at the patient level. They are useful for looking at subject-specific data and for helping to provide some context around a specific safety issue as it pertains to individual subjects where the safety issues applies. They are also useful in helping to rule out and/or confirm certain safety characteristics or patterns and implications therein. Without programming support, preparing narratives is a labor intensive exercise (Figure 1). After statistical report (such as CSR) is generated, safety issues or concerns are identified which requires further investigation. Medical writers will typically add narrative information into the original statistical report and this gets further evaluation from Pharmacovigilance (PV). Preparing narratives usually require aggregation of information from different listings for each subject and summarizing in statements about the subjects experience regarding the event of interest. Per the ICH-E3 guideline, narratives of deaths, other SAEs, and other significant adverse events judged to be of special interest, such as hepatotoxicity events, renal safety events, cardiotoxicity, torsades de pointe, and so on should be provided. To quote ICH-E3 - 12.3.2 Narratives of Deaths, Other Serious Adverse Events, and Certain Other Significant Adverse Events:

“There should be a brief narrative describing each death, other serious adverse event, and other significant adverse event that is judged to be of special interest because of clinical importance. These narratives can be placed either in the text of the report or in section 14.3.3, depending on their number. Events that were clearly unrelated to the test drug/investigational product may be omitted or described very briefly. In general, the narrative should describe the following: The nature and intensity of event; the clinical course leading up to event, with an indication of timing relevant to test drug/investigational product administration; relevant laboratory measurements; whether the drug was stopped, and when; countermeasures; post-mortem findings; investigator's opinion on causality and sponsor's opinion on causality, if appropriate”.

Figure 1: A typical process for producing narratives

Generally, the narrative will require patient identifier, demographic information, and other relevant information pertaining to the events of special interest, such as, concomitant and previous illnesses, details of timing and duration and relevant concomitant and previous medication. Before PAN was implemented, medical writing and/or PV will usually take source information and write out a narrative for the safety event of interest for each subject where it applies. As an example, a narrative may sound something like:

“A 100-year old male patient who is a current smoker with a history of hypertension, stroke, and chronic asthma was randomized to drug XX mg on 05-12-2012. The subject experienced an MI on Day 14 after start of taking drug XX. Concomitant medications at the time of the event were acenocumarol, metformin, bicalutamide, atorvastatin, and persantin. The subject was admitted to hospital on same day of the event. It was reported that he had first experienced worsening symptoms in late April 2012. The event was reported as resolved on 05-19-2012 and the subject was discharged on the same day. Laboratory results were also reported as normal at discharge. No change was made to the study medication dose. The investigator considered the event was unrelated to study medication.”

As can be noted from the above example, the narrative draws from several data sources, including demographics data, drug dispensing data, concomitant medications, medical history data, adverse events, laboratory data, and CIOMS. A well-written narrative should present the information chronologically and medically make sense while at the same time identifying and relating the relevant information of interest in a consistent way. If the description, in terms of format, of the narrative for each subject is identical across all subjects, then it is possible to create programs that produce the narratives using SAS. This approach was discussed, for example, by Izzard and Simms (2011) and York and Martin (2009).

PROGRAMMED ASSISTED NARRATIVES (PANs)

To ease the burden of going through thousands pages of listing output, one can make use of programmed assisted narratives (PANs). PANs can be used to provide information that is useful in putting together narratives in the form of targeted and focused patient profiles. They are by-patient numeric and text listings organized by domain and include targeted data needed for narratives addressing a specific issue. They allow for consolidation of information about the important domains in one place without having to look at multiple listings for the subject’s data. Generally, the first step required for a more targeted data review is to identify the exact needs of the end user and ensure that all pertinent data are included. The information in PANs could include patient identifier, demographic information, and other relevant information pertaining to the adverse events of special interest, e.g., based on an SMQ, specific concomitant and previous illnesses, details of timing and duration and relevant concomitant/previous medication with details of dosage, and special labs if applicable. A typical output for a PAN has a cover page as shown below (Figure 2.1).

Figure 2.1 Cover Page of PAN

Protocol: xxxxxx-xxxx Page 1 of 1

Information for Subjects with Markedly Abnormal LFT Values
Cover Page

<u>Site</u>	<u>Subject</u>	<u>Initial Treatment</u>	<u>MedDRA Preferred Term</u>	<u>Relationship to Study drug</u>
1010	1010003	XX 30 mg QD	pnhangBlood cholesterol increased	Possible
	1010028	XX 30 mg QD	pnhangBlood triglycerides increased	Possible
	1010078	XX 30 mg QD	pnhangBlood triglycerides increased	Probable
	1010153	XX 30 mg QD	pnhangBlood triglycerides increased	Probable
			pnhangGamma-glutamyltransferase increased	Not Related
	1010178	XX 30 mg QD	pnhangBlood triglycerides increased	Possible
			pnhangBlood cholesterol increased	Possible

The cover page includes a list of subjects who met the identified issues (such as AE of special interests, a set of lab criteria, etc...). For each subject listed, an individual narrative output file is generated using SAS program for PANas shown in Figure 2.2-2.4 below:

The ODS section of the program used to generate these output is included in Appendix A. The program calls a customized template "panrtf" which was defined using PROC TEMPLATE. The ODS section of the program are defined into two sections. The first section is for the cover page shown in Figure 2.1. The second section calls a macro to automatically output one PAN file for each subject listed in the cover page. Within that section, the ODS options "newfile=none" and "startpage" are used to control when a page break should be inserted.

USE OF GRAPHS TO SUPPORT NARRATIVE WRITING

Of note from Figure 2.1-2.4, PANs in themselves are useful in the sense that only key focused information is included. Hence, the end user can quickly have all the information needed available readily without having to plough through pages and pages of line listings or non-focused output. However, it is not easy to quickly capture or identify data relationships from the PANs based on alphanumerical output alone. Hence writing narratives more fluidly and easily can benefit from the use of graphical output. As the saying goes, "a picture is worth a thousand words". Graphical output to support alphanumeric text output has become increasingly important. For this purpose, it is useful to supplement PANs with graphical output which helps to quickly provide some insight into various relationships in the data, such as, which AEs were reported at the same time with the certain concomitant medications, or elevations of liver enzymes.

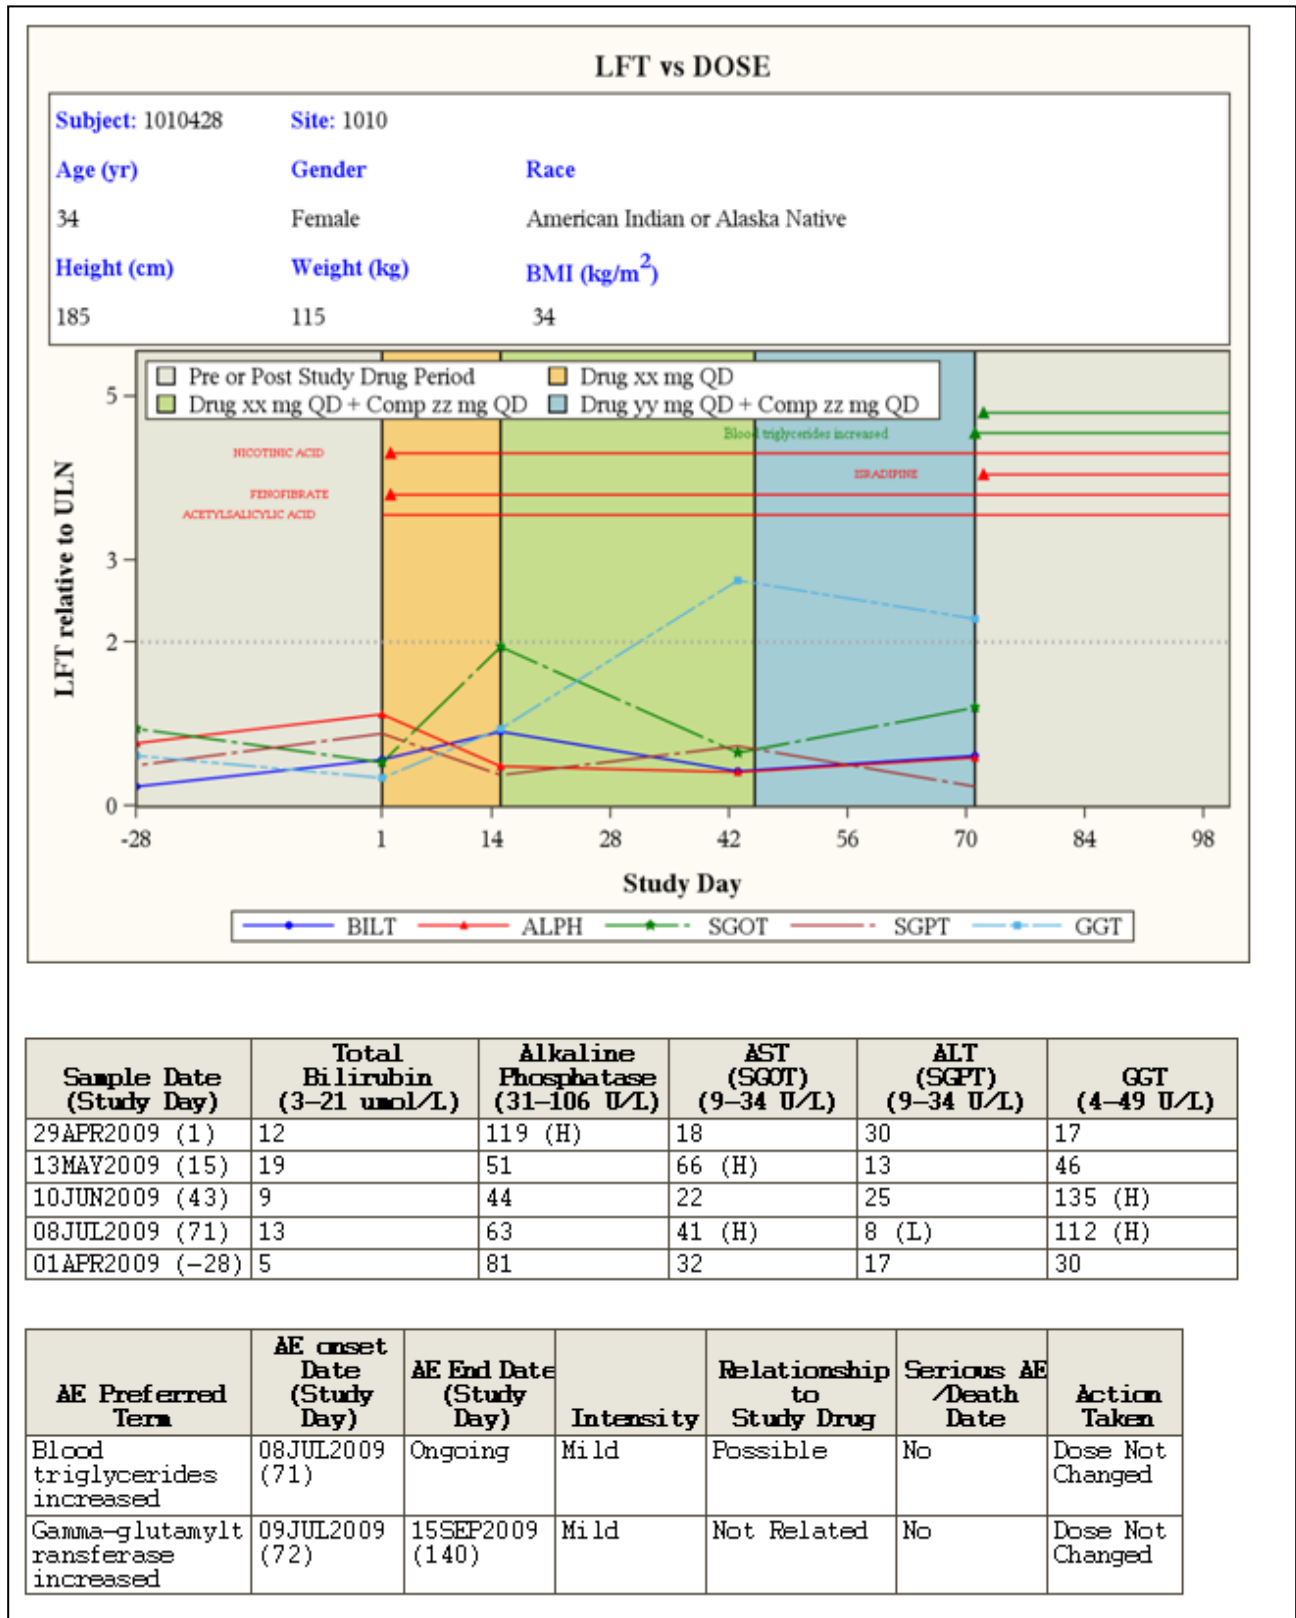

Figure 3 – Graphical PAN

In Figure 3, AEs (green lines and texts), lab data (bottom part of graph), and concomitant medications (red lines and texts) can be presented on the same timeline taking advantage of color schemes to point out key aspects of the data characteristics and relationships. One can also use the graph to see the relationship between laboratory measurements of interest to see if they trend together; if a specific medication was given following the occurrence of specific adverse event of interest, or if a specific lab test value changed shortly after exposure to study drug or other drugs. Clearly a comprehensive visualization of various data from

various domains can also help the end user to efficiently identify potential safety issues and hence from this point of view the graphical presentations offer an obvious advantage over the traditional alphanumeric text output as it is not easy to visualize the timing of events in this format.

Figure 4: Integrated Alphanumeric and Graphical PAN

INTEGRATION OF TEXT AND NUMERIC OUTPUT WITH GRAPHS IN PANs

As noted already, for PANs with text output alone, it is not easy to readily see the relationships between the various data sources. On the other hand, an entirely graphical output does not render itself useful from writing a narrative without providing data. An optimal solution is to create PANs that combine graphical output and data. This can help writing of narratives more efficient and allowing the end user to quickly spot data relationships. An example of a PAN that integrates alphanumeric and graphical output is provided in Figure 4.

The integration of graphical output in the PANs allows the end user to quickly identify data relationships and use this along with specific details of data values available in the alphanumeric output when writing the narrative, all in one source. The sample SAS program used to generate this kind of output is included in Appendix B. The first section of code can also be used to generate graphical only output as shown in Figure 3. In this section, the graphics are defined in GTL template "labplot". Subject information were output with "entry" commands. Using blockplot, the study drug periods can be identified with different color panels. Adverse Events of special interests (in this case, AE related to LFT) and Medications taken within two weeks of these AEs are plotted with green and red colors, respectively. The ratios of lab values relative to the upper normal limits (ULN) are presented at the bottom part of the graph. It makes possible to plot multiple lab parameters within a single scale by using the ratio of lab value relative to ULN. However, it is not easy to identify individual lab values in its original unit, so as well detailed AE information. Therefore, the second section of program produces two tables (lab and AE) using PROC REPORT procedures to provide detail data related to the graph. Using this approach helps to provide the information needed for preparing narratives available in one source. The same program can also be easily modified to plot other lab or vital sign parameters based other special safety concerns.

CONCLUSION

In this paper we tried to make a couple of arguments, namely, PANs can be a useful resource for writing narratives. They allow for consolidation of key information that is needed for narratives be available in one place. The PANs are not only useful in meeting operational objectives of writing narratives and aid in the creation of the submission documents, but they are also useful in assessing the safety profile of drugs. This way, the end user can look at information about all important data domains and characteristics in one place without having to look at multiple tables and graphs. Another point brought forward is that one can supplement PANs with graphs to help readily identify data relationship and hence also make writing of narratives more efficient. More importantly, we showed that one can integrate alphanumeric text with graphs in the PANs so as to maximize their value as resource for writing narratives and also potentially use them for submission purposes. The PANs when integrated with graphs can be highly customized to the needs of the users. We also illustrated how this can easily be done within the SAS environment using SAS ODS and SAS GTL. In this regard, SAS possesses the tools to efficiently provide customizable PAN outputs that allow the end user to have all the information in one place and to quickly and easily visualize and identify the key characteristics of subjects' data with respect to a specific safety concern of interest.
